A SPECIAL PUBLICATION OF THE
RECORDS OF THE HAWAII BIOLOGICAL SURVEY FOR 1998

RESEARCH PUBLICATIONS OF BISHOP MUSEUM

Research publications of Bishop Museum are issued irregularly in the following active series:

- *Bishop Museum Occasional Papers*. A series of short papers describing original research in the natural and cultural sciences. Publications containing larger, monographic works are issued in four areas:
- *Bishop Museum Bulletins in Anthropology*
- *Bishop Museum Bulletins in Botany*
- *Bishop Museum Bulletins in Entomology*
- *Bishop Museum Bulletins in Zoology*

Numbering by volume of *Occasional Papers* ceased with volume 31. Each *Occasional Paper* now has its own individual number starting with Number 32. Each paper is separately paginated.

The Museum also publishes *Bishop Museum Technical Reports*, a series containing information relative to scholarly research and collections activities. Issue is authorized by the Museum's Scientific Publications Committee, but manuscripts do not necessarily receive peer review and are not intended as formal publications.

Institutions and individuals may subscribe to any of the above or purchase separate publications from Bishop Museum Press, 1525 Bernice Street, Honolulu, Hawai'i 96817-0916, USA. Phone: (808) 848-4135; fax: (808) 841-8968; email: press@bishopmuseum.org.

Institutional libraries interested in exchanging publications should write to: Library Exchange Program, Bishop Museum Library, 1525 Bernice Street, Honolulu, Hawai'i 96817-0916, USA; fax: (808) 848-4133; email: libex@bishopmuseum.org.

Hawaiian Vascular Plants at Risk: 1999¹

WARREN L. WAGNER² (Department of Botany, MRC 166, National Museum of Natural History, Smithsonian Institution, Washington, D.C. 20560-0166, USA; email: wagner.warren@nmnh.si.edu), MARIE M. BRUEGMANN² (Pacific Islands Office, U.S. Fish and Wildlife Service, 300 Ala Moana Blvd., Rm. 3122, P.O. Box 50088, Honolulu, Hawai'i 96850, USA), DERRAL R. HERBST (Research Associate, Hawaii Biological Survey, Bishop Museum, 1525 Bernice Street, Honolulu, Hawai'i 96817-2704, USA), & JOEL Q.C. LAU (The Nature Conservancy of Hawaii, Hawaii Natural Heritage Program, 1116 Smith St., Honolulu, Hawai'i 96817, USA)

Hawai'i has more endangered and threatened plants than any other state in the United States (263/699 taxa or 38% U.S. listed vascular plants). Because of the magnitude of the conservation problems in the Hawaiian Islands, it is vital that biologists, conservationists, and land managers have the most up-to-date information possible. This 1999 assessment of Hawaiian vascular plant species at risk is an update of the compilation provided by Wagner *et al.* (1990). It is derived from a database maintained in the Pacific Island program in the Department of Botany, Smithsonian Institution. Since the 1990 assessment, much attention has been focused by many individuals and organizations on evaluating Hawaiian ecosystems and the species that comprise them. Basic research on the flora has been conducted as well as considerable effort expended to survey, conserve, and manage the dwindling and degrading natural habitat throughout the state. In order to make this 1999 assessment comprehensive, other authors representing current efforts (which include database development) in Hawai'i to compile and track information on at risk plants were invited to participate (and are listed alphabetically on the title page). It also was important to add the pteridophytes to the database because they have not been evaluated much previously.

Several other organizations have ongoing databases to track the conservation status of Hawaiian plants. Therefore, in addition to our evaluation, we also have brought together here the other three principal systems in Hawai'i. U.S. Fish and Wildlife Service (Service), and the Hawaii Natural Heritage Program of The Nature Conservancy of Hawaii (HINHP) provided data sets that were combined into the database at the Smithsonian Institution. Additionally, the status ratings for Hawaiian taxa included in a recent global review, the 1997 IUCN *red list of threatened plants* (Walter & Gillett, 1998) were incorporated into the Smithsonian database. The 1999 list below is derived from this database. It soon will be available on the web (<http://www.nmnh.si.edu/departments/botany.html>, under Research).

One of the primary reasons for publishing the 1999 list is to provide what we, the authors, feel is the most up to date possible overall assessment. Another objective for this compilation is to provide all of the other systems for Hawai'i (US, HINHP, and IUCN) side by side so that comparisons can be made directly and easily. When there are differences in ranking between the systems for a particular taxon we hope to stimulate further evaluation of that taxon so that its status can be refined.

United States Endangered Species Act

It has been nearly a quarter century since the first comprehensive enumeration of rare

1. Contribution No. 1999-023 to the Hawaii Biological Survey.

2. Research Associate, Hawaii Biological Survey, Bishop Museum, 1525 Bernice Street, Honolulu, Hawai'i 96817-2704, USA.

and endangered species of Hawaiian plants was made by F.R. Fosberg and D.R. Herbst (1975). These authors were well aware that their assessment of the endangered status of the Hawaiian flora lacked a strong biological basis and thus was inaccurate and misleading. However, it was an important step in evaluating the status of the unique Hawaiian flora. The data was subsequently utilized by the Smithsonian Institution when the Institution was directed under the auspices of the enactment of the United States Endangered Species Act of 1973 (ESA) to prepare a *Report on endangered and threatened plant species of the United States*. This report was transmitted to the Congress on 9 January 1975 and published as a notice of review by the Service on 1 July 1975, and in somewhat revised form published by the Smithsonian (Ayensu & DeFilipps, 1978). In response to the 1975 notice of review, the Service published a proposed rule in the *Federal Register* on 16 June 1976 to determine endangered status for approximately 1,700 vascular plant taxa. The list of 1,700 plant taxa was compiled by the Service, based upon the comments and information received in response to the July 1975 notice of review. In 1978, amendments to the ESA required that all proposals over two years old be withdrawn. This was done on 10 December 1979. Updated notices of review have been published periodically since then. At the time of the 1975 notice of review, about 10% of the United States flora and 50% of the Hawaiian flora was considered at risk.

The Fosberg and Herbst (1975) publication was the basis of the Hawaiian taxa included on all subsequent lists of candidate threatened and endangered plants published by the Service's endangered species program until it was revised in 1990 (e.g., a complete review, published in 1985, listed 748 candidate taxa). Many of the taxa recognized in 1975 were not based upon sound biological principles, which at that time made the implementation of programs to protect endangered plants in the Hawaiian Islands less discerning and prevented an accurate assessment and inventory of endangerment in the flora. In 1978, *Vicia menziesii* Spreng. was the first Hawaiian species listed under the ESA (McManus, Altevogt & MacBryde, 1978). Nineteen Hawaiian taxa were federally listed as endangered during the next decade. At the time the manuscript for the *Manual of the flowering plants of Hawai'i* (the *Manual*; Wagner *et al.*, 1990) was submitted for publication, 19 Hawaiian plants taxa had been federally listed either as threatened or endangered; that number is now 263. In the ESA, the Service defines a species to include any subspecies of fish or wildlife or plant. The official number of endangered and threatened "species" for Hawai'i (263) is different than the actual number of taxa (285) for 2 reasons: 1) the federal list lags behind the recent changes in taxonomy due to the Service's listing priority policy and the time required to process these changes, and 2) if a species with infraspecific taxa is listed in one rule-making, only the full species is counted on the federal list, but if infraspecific taxa of the same species are in two or more rule-making, then it counts as two or more.

United States definitions

The listing process is one of the basic functions performed by the Fish and Wildlife Service in carrying out its responsibilities under the ESA. In order to list, reclassify, or delist a species, the Service must follow a strict legal process known as a "rule-making" (regulatory) procedure (see http://www.access.gpo.gov/su_docs/dbsearch.html). The rule is first proposed in the *Federal Register*, a U.S. government publication. After a public comment period, the Service decides if the rule should be approved, revised, or with-

drawn. The process takes up to a year, or longer in unusual circumstances, and encourages the participation of all interested parties, including the general public, the scientific community, other government agencies, and foreign governments.

Once an animal or plant is listed, all protective measures authorized by the ESA apply to the species and its habitat. Such measures include protection from adverse effects of Federal activities; restrictions on taking, transporting, or selling a species; authorization for the Service to develop and carry out recovery plans; the authority to purchase important habitat; and Federal aid to State and Commonwealth wildlife agencies that have cooperative agreements with the Service.

The Service has developed a priority system designed to direct its efforts toward the plants and animals in greatest need of protection. The magnitude of threat is the most important consideration, followed by the immediacy of the threat and the taxonomic distinctiveness of the species (the most distinctive is a monotypic genus, then a full species, and lastly a subspecies, variety, or vertebrate population).

- E The term “endangered species” means any species which is in danger of extinction throughout all or a significant portion of its range other than a species of the Class Insecta determined by the Secretary to constitute a pest whose protection under the provisions of this Act would present an overwhelming and overriding risk to man. There are 6 infraspecific taxa that are presumably extinct that are members of listed endangered species that are not extinct; they are designated by “ex” rather than E in this list.
- T The term “threatened species” means any species which is likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range if the threats are not controlled.
- C Candidate species are those plant and animal species for which the Fish and Wildlife Service has sufficient information on their biological status and threats to propose them as endangered or threatened under the ESA.
- PE Species that the Fish and Wildlife Service has proposed as endangered under the ESA. Proposals are published in the *Federal Register*.
- No Status. These include taxa that have not been through the formal federal process. This also includes species that warrant candidate status but have not been processed.

The 1999 assessment and the Hawaiian flora project

As part of the Hawaiian flora project at Bishop Museum from 1982-1988, available information concerning threats and decline to the native species was gathered. The IUCN categories indicating degrees of threat to native species were adopted from the *IUCN plant red data book* (Lucas & Synge, 1978) for use in the resulting *Manual* (Wagner et al., 1990), with minor modifications. In the context of a greatly revised taxonomy the authors compiled a much more accurate census of at risk plants in the state. Of the 1,094 taxa of native flowering Hawaiian plants recognized by Wagner *et al.* (1990), 423 (38%) were considered to be extinct or at risk; of these taxa, 107 were presumed extinct (10% of the native taxa), 139 endangered (12%), 39 vulnerable (4%), and 138 rare (12%). The assignment of these categories was still subjective, but was based upon better and more complete biological information than was available during the development of previous

Hawaiian lists of at risk species described above. The conservation status rankings in the *Manual* were used by D. R. Herbst as the basis for revising the United States candidate list for endangered species, one of his duties in the endangered species program of the Service; the revised list was published in the *Federal Register* in February 1990. This list and the *Manual* were used in an out-of-court settlement (when the Sierra Club Legal Defense Fund filed suit against the U.S. Fish and Wildlife Service, see *Hawaiian Botanical Society Newsletter* 29(1), 1990), which mandated the listing of more than 150 additional species, hiring more botanists, and providing more funding).

Since the mandatory cut-off date for incorporation of new information in the *Manual* in 1987, attempts have been made to record all changes and corrections to the information in the *Manual*. The initiation of the Hawaii Biological Survey (HBS) by the Hawaii State Legislature in 1992 as a program of Bishop Museum has greatly helped in this task. The HBS was created to locate, identify, and evaluate all native and non-native species of flora and fauna within the State and to maintain the reference collections of that flora and fauna. In coordination with related activities in other federal, state, and private agencies, the HBS will gather, analyze, and disseminate the biological information necessary for the wise stewardship of biological resources in the Hawaiian Islands (see web page at <http://hbs.bishopmuseum.org/> for further information). Since 1994, the HBS has published the annual *Records of the Hawaii Biological Survey*. The *Records* comprise short papers listing new state or island records of various plants and animals, as well as longer papers describing new taxa or reviewing certain aspects of the islands' flora and fauna.

Since publication of the *Manual* (Wagner *et al.*, 1990) research has continued in the new context of the extensive revisions presented in the *Manual*, further refining the taxonomic framework of Hawaiian angiosperms. The goals of Wagner and Herbst and collaborators have continued to focus on phylogeny and improved taxonomy of Hawaiian angiosperms, understanding nomenclature, and tracking and stimulating collection and study of the flora. We have continued to accumulate information toward a revised edition of the *Manual*. Related projects include, preliminary papers for the revised edition (taxonomic realignments, e.g., Wagner & Weller, 1991; description of new species, e.g., Lorence & Wagner, 1995; new records of naturalized species, range extensions, rediscoveries of presumed extinct species, and nomenclatural changes, e.g. Herbst & Clayton, 1998, and an updated checklist); assessment and data basing of all published names for Hawaiian angiosperms; monographic and revisionary work on such groups as Hawaiian *Cyrtandra* (Gesneriaceae), and *Schiedea* and *Alsinidendron* (Caryophyllaceae); phylogenetic and biogeographic analyses to examine patterns of speciation and evolution distribution within the Hawaiian Islands relative to geological history and ecological diversity (e.g., Wagner & Funk, 1995); investigation of reproductive systems of Hawaiian angiosperms relative to such factors as island age and ecological parameters, as well as a comparison of island to continental areas (Sakai *et al.*, 1995a, 1995b).

The manuscript for the *Manual of the flowering plants of Hawai'i* was completed more than ten years ago. Because of the availability of the *Manual*, field work during this period has been more focused than in preceding decades, particularly that concerning the naturalized flora and rare native plants at risk of extinction. Similarly, numerous field studies for systematic research, conservation, and land management have been conducted by private, state, and federal organizations. Thirty-three new taxa of native flowering plants have been discovered. Two-thirds of these are from Kaua'i, thanks largely to col-

lection efforts by the National Tropical Botanical Garden. Field studies have resulted in the rediscovery of 35 species presumed extinct, the resurrection of 25 taxa relegated to synonymy in the *Manual*, and more precise information on the condition of much of the endemic and indigenous flora. These are enumerated in a forthcoming revised edition of the *Manual* (Wagner *et al.*, 1999).

A significant development for Hawaiian conservation was the designation in 1989 of the Hawaiian Islands by the Center for Plant Conservation (CPC) as one of its priority conservation regions. Their program emphasized inter-institution coordination and expanded its *ex situ* conservation program into the state. In June 1989 the CPC organized the first Hawai'i Endangered Plant Task Force meeting in Honolulu. The task force, comprising Hawaiian botanists, established conservation priorities for the rarest plants. In 1991 the CPC engaged additional Hawaiian botanical gardens in their *ex situ* conservation program; currently there are five gardens participating in the program. Each of the gardens was given a small grant to maintain selected plants in their collection and preserve propagules of the species. As of March 1998, 73 Hawaiian species were in the CPC National Collection of 550 plants. We have indicated the plants in the national collection in the list presented here. We have indicated each of these by a bolded asterisk (*) several spaces after the distribution entry of the taxon. This is followed by a capital letter indicating the Hawaiian botanical garden that is managing the *ex situ* conservation of the taxon (G = Amy B.H. Greenwell Ethnobotanical Garden; H= Honolulu Botanical Gardens; L = Harold L. Lyon Arboretum; N = National Tropical Botanical Garden; W = Waimea Arboretum and Botanical Garden). See the CPC web page for more information at <http://www.mobot.org/CPC/>. In 1992 the Center established a Hawai'i Program Office at the Bishop Museum with the museum botanist, Loyal Merhoff, as part-time project coordinator. A major accomplishment was the organization of an ongoing annual meeting of Hawaiian botanists to review the list of at risk species, resulting in a database established on this information. Merhoff later became the U.S. Fish and Wildlife Service Botanist and transferred a version of this database to Service's data files. In recent years, both the CPC and the Service's databases are being maintained and have incorporated updates from the annual meetings. The Service's version was made available to Wagner in 1997, and, in conjunction with taxonomic updates, herbarium work, and input from Hawaiian botanists, was used to update the Smithsonian Institution data, which had been based on the *Manual* and subsequent literature, as well as information from specimens that had been collected in the past decade.

The Center for Plant Conservation maintains two databases on rare Hawaiian plants at its Hawai'i office now located at the Lyon Arboretum. The larger of these databases focuses on *ex situ* holdings of rare Hawaiian plants in botanical gardens while the other contains rare Hawaiian plant monitoring information, principally from O'ahu. These databases are being upgraded and combined, and were not available at the time this paper was written. Information in these databases will be included in the Smithsonian data basing efforts once this merge is completed.

During the development of the 1999 assessment we have brought together the expertise of the personnel of the Bishop Museum, The Nature Conservancy, the Smithsonian Institution, and the U.S. Fish and Wildlife Service. Programs at Bishop Museum and the Smithsonian are primarily focused on the biology, classification and evolution of organisms. The Service is responsible for assessing and listing at risk taxa under the United

States Endangered Species Act of 1973 (ESA), while the HINHP maintains a database incorporating information on the rare plants, animals, and natural communities of Hawai'i used in conserving native plants, animals and ecosystems. The HINHP maintains its database in its goal to aid the community to conserve native plants, animals, and ecosystems, and to provide an updated evaluation of the vascular plants at risk. The evaluation symbol in bold in the 1999 column represents the consensus of all four authors on the status of the taxon. Wagner initially ranked all of the taxa using the sources of information discussed below, after which the other authors reviewed the taxa, discussed them if opinions differed, and modified the list accordingly. The resulting 1999 list is a synthesis of our perspectives and knowledge. We have each brought our separate knowledge of the status of the taxa gained through interaction with the Hawaiian botanical community and from information generated through field work and our respective programs. Our intent was to compile available information into a convenient format, so that it could be used by interested individuals. The 1999 list provides the most current status of Hawaiian plants at risk, allowing the efforts to conserve these taxa and their ecosystems to be as focused as possible. The listing of plants by the Service lags well behind the biological assessment that a particular taxon is of concern or at risk of extinction because of the lengthy legal procedures required for formally listing a species as threatened or endangered and the need for sufficient written data to support listing.

Conservation status definitions for the 1999 assessment

The categories used to indicate degrees of threat to native species have been adopted from the *IUCN plant red data book* (Lucas & Synge, 1978) for use in the *Manual* (Wagner et al., 1990), with modifications. We continue the same categories for the 1999 assessment. The assignment of these categories is subjective but is based upon better and more complete biological information than was available during the development of previous lists of endangered species. The *IUCN plant red data book* has four categories indicating degree of threat: extinct, endangered, vulnerable, and rare. The definitions given below are essentially the same as those used by Wagner et al. (1990).

- EX** Extinct: This category is used for species for which we have no evidence that they are extant. As many Hawaiian plants are very restricted in their distribution, some species presently placed in this category undoubtedly will be rediscovered. A question mark (**EX?**) is added after this category when a taxon has not been collected for decades or the known occurrences are no longer extant, but cast some doubt due to the lack of recent or specific information. An "H" (**EXH**) is added after this category for taxa with extra-Hawaiian distribution, but with no known extant Hawaiian populations remaining.
- E** Endangered: These are taxa in danger of becoming extinct throughout all or a significant portion of their range unless the threats jeopardizing their survival are alleviated. An "H" (**EH**) is added after this category for taxa with extra-Hawaiian distribution, which are in endangered throughout all or a significant portion of their range in the Hawaiian Islands.
- V** Vulnerable: This category includes taxa likely to become endangered in the near future unless the threats to their survival are removed or reduced. In the Hawaiian Islands, most species in this category are threatened by extensive habitat destruction or modification or by other environmental disturbances. An

- “H” (**VH**) is added to this category for taxa with extra-Hawaiian distribution that have imminent threats to the populations in the Hawaiian Islands.
- R** Rare: Many Hawaiian plants have small, localized populations. Species not believed to be endangered or vulnerable at present, but that could be considered at risk, are included in this category. An “H” (**RH**) is added to this category for taxa with extra-Hawaiian distribution that have small, localized populations in the Hawaiian Islands.
- AS** Apparently Secure: We do not believe that many of the Hawaiian plants included in one or more of the databases warrant being given an at risk rank. We indicate these plants with the AS designation. These taxa are usually restricted in geographical range if given HINHP rank of G3, and an AS by us, or are too widespread, abundant, or seemingly secure to warrant listing.

Several factors were considered in making the determinations, including:

1. The number of collections of each taxon in the BISH, PTBG, or US collections and the date of the most recent collection. Taxa with few collections or that have not been collected in the last 40–50 years usually are listed as “rare” or “extinct.” Assignment to one of these two categories was determined by our knowledge of the quality of its habitat. For example, if the plant is restricted geographically to a remote, relatively undisturbed area, we usually assume that its population is relatively stable. However, if the number of individuals of a species becomes small or there is a clear threat, such as destruction by pigs, goats, or other feral animals or they lose the ability to reproduce, the species is categorized as “endangered.”
2. Personal knowledge of the species and the condition of its habitat. Botanists and knowledgeable naturalists were interviewed and their field observations have contributed substantially to our evaluations.
3. The geographical location or habitat type. Some ecosystems are more sensitive or more susceptible to degradation than others. This includes the potential for development or change; for example, many plants of coastal areas are considered “vulnerable,” as much of this habitat is being developed.
4. Distribution. Species found on several islands usually were not placed into one of the IUCN categories, because a single disaster, human-caused or natural, would not cause their extinction. Exceptions to this are, of course, situations where there is a clear threat to a species throughout its range, especially when it has become extirpated on one or more islands.
5. Nature of, and potential for, threats. There is much greater potential for the destruction of a species by human disturbance than by natural causes. For example, today more native species are destroyed by human-caused fires than those set by volcanic eruptions. Feral animals such as pigs, goats, sheep, and cattle have degraded vast areas of natural habitat in the Hawaiian Islands and pose one of the major threats to the native ecosystem and its components. Alien plants, which cover an enormous amount of land area in the Hawaiian Islands, are among the greatest problems, as are introduced rats, diseases, and insects.

Hawaii Natural Heritage Program

The Hawaii Natural Heritage Program (HINHP) of The Nature Conservancy of

Hawaii also maintains a database incorporating information on the rare plants, animals, and natural communities of the Hawaiian Islands. Rare plant information gathered includes collection data from specimens at Hawaiian herbaria (BISH, PTBG, HLA, HAW), observations by field botanists, and data from published and unpublished literature. Additional information is derived from biological surveys conducted by HINHP on state, federal, and private lands. For each rare plant occurrence the available information is summarized in a database record, and the occurrence is plotted on maps and in a Geographic Information System. HINHP was initiated in 1985. At its inception, the HINHP obtained from the U.S. Fish and Wildlife Service files that D. Herbst developed for all threatened and endangered Hawaiian plant species, including label data from BISH specimens, copies of pertinent literature, notes on present status based upon his and other botanist's field knowledge. These files were made available to HINHP volunteers at the initiation of the program. The idea was to share information, as all were working toward the same goal. An advisory committee consisting of experienced field botanists was tasked to develop a list of plant taxa considered to be rare and endangered; information would be gathered for these species and added to the HINHP database. Subsequently, HINHP has continued to solicit updated opinions on the rarity and endangerment of Hawaiian plant taxa from botanists with field knowledge. Such opinions, in addition to the information contained within the HINHP database, have been used to rank Hawaiian plant taxa using HINHP's endangerment ranking system.

The Hawaii Natural Heritage Program assesses the status of all taxa in the flora, not just rare species, using criteria employed throughout the natural heritage network (Master, 1991). These status assessments focus on the potential risk of extinction of a species as measured by its rarity and known or potential threats to its continued existence. In general, status ranks of G1 through G3, GH, and GX can be considered to indicate at-risk species that should be regarded as being of conservation concern.

Hawaii Natural Heritage Program's Global Rank Definitions

- G1 (or T1 for infraspecific taxa): Critically imperiled globally. 1–5 occurrences and/or fewer than 1,000 individuals remaining; or more abundant but facing extremely serious threats range-wide.
- G2 (or T2 for infraspecific taxa): Imperiled globally. 6–20 occurrences and/or 1,000–3,000 individuals remaining; or more abundant but facing serious threats range-wide.
- G3 (or T3 for infraspecific taxa): Vulnerable globally; 21–100 occurrences and/or 3,000–10,000 individuals remaining; or more abundant but facing moderate threats range-wide; or restricted in range.
- G4 (or T4 for infraspecific taxa): Widespread, abundant, and apparently secure, but with cause for long-term concern.
- G5 (or T5 for infraspecific taxa): Demonstrably widespread, abundant, and secure.
- GH (or TH for infraspecific taxa): Historical or possibly extinct. No recent observations, but there remains a chance of rediscovery.
- GX (or TX for infraspecific taxa): Presumed extinct. No recent observations, and there does not appear to be a chance of rediscovery.
- C Persisting in cultivation.
- No Status. For the purposes of this paper we have included only the GX, GH,

and G1 through G3 taxa from the HINHP database. Many of the taxa included in this list that did not receive one of these HINHP rankings would be a G4 or G5. However, we can not assign the “apparently secure” designation used in the 1999 assessment because some taxa, including those recently described or recognized as a result of taxonomic change, are not included in the HINHP database at all yet and may well soon receive other than a secure rating. We thus identify all taxa that do not have GX, GH, G1, G2 or G3 rating a “No Status” designation.

1997 IUCN Red List

The 1997 IUCN red list was based largely on earlier versions of the Hawaii Natural Heritage Program’s data. The Nature Conservancy provided status assessments to IUCN on all U.S. plants in the Natural Heritage Central Databases ranked G3 (globally vulnerable) or more rare. For purposes of this publication Natural Heritage global ranks were then converted into IUCN threat categories based on the following general principals: G1 = Endangered; G2 = Vulnerable; G3 = Rare (Walter & Gillett, 1998). Unfortunately, in the massive data conversion and reconciliation process that went into compiling the 1997 IUCN red list of threatened plants (covering more than 33,000 plant species from 2,091 sources of information), data conversion errors occurred (B. Stein, pers comm.). In addition, some older information was not overwritten by the more current Heritage Program data, resulting in duplicate, and at times conflicting status listings and distributional information. The Hawaiian data were abstracted from the publication into the Smithsonian database. In cases where there were double entries for a taxon (and the ratings differed) Wagner selected the one that seemed most current. In cases where there were species-level and infraspecific-level ratings the infraspecific ones were used if ratings differed. For example, *Cyanea superba* is given an E rating, while *C. superba* subsp. *regina* is given an Ex/E and *C. superba* subsp. *superba* is given an E. We give only taxon ratings and thus entered the two subspecies ratings. In the few cases where the current taxonomy subdivides a species and the IUCN gave only a species-level rating; it was entered for both taxa. Finally, in cases where the IUCN listing differed in taxonomic concept they were converted to the taxonomy used here or omitted if currently considered a taxonomic synonym.

The 1997 IUCN Red List Categories

The *1997 IUCN Red List of Threatened Plants* is based on the pre-1994 IUCN Categories, drawn up by the IUCN Species Survival Commission. These have since been revised (IUCN, 1994).

- Ex EXTINCT: Taxa not definitely located in the wild during the past 50 years.
- Ex/E EXTINCT/ENDANGERED: Taxa that are suspected of having recently become extinct.
- E ENDANGERED: Taxa in danger of extinction and whose survival is unlikely if the causal factors continue operating. Included are taxa whose numbers have been reduced to a critical level or whose habitats have been so drastically reduced that they are deemed to be in immediate danger of extinction. Also included are taxa that may be extinct but have definitely been seen in the wild in the past 50 years.
- V Taxa believed likely to move into the “Endangered” category in the near future

- if the causal factors continue operating. Included are taxa of which most or all the populations are decreasing because of over-exploitation, extensive destruction of habitat or other environmental disturbance; taxa with populations that have been seriously depleted and whose ultimate security has not yet been assured; and taxa with populations that are still abundant but are under threat from severe adverse factors throughout their range.
- R RARE: Taxa with small world populations that are not at present “Endangered” or “Vulnerable”, but are at risk. These taxa are usually localized within restricted geographical areas or habitats or are thinly scattered over a more extensive range.
- I INDETERMINATE: Taxa that are known to be “Endangered”, “Vulnerable”, or “Rare” but where there is not enough information to say which of the three categories is appropriate.
- No Status. Some of these taxa would probably be rated as “apparently secure” while others are at risk, but for various reasons (mostly recently published or altered taxonomy) were not included in the publication.

Comparison of the lists

The comprehensive list presented below of Hawaiian vascular plants includes 904 of 1342 native taxa currently recognized with an at risk or of concern rating in at least 1 of the 4 systems included. The taxonomy follows W.L. Wagner & D.R. Herbst (1999) for the angiosperms, and W.H. Wagner, F. Wagner & D. Palmer (unpublished) for the pteridophytes. The list includes all taxa with status in one or more of the 4 ranking systems. The majority of the list consists of dicots (971 of 1004 taxa; 79%), followed by monocots (70 of 155 taxa; 45%); also included is *Eragrostis leptostachya* formerly thought to be an extinct endemic, *E. hosakai*, and a low portion of pteridophytes (42 of 183 taxa; 23%).

The 1999 at risk ratings given here include 638 of the 904 taxa of vascular plants in the overall list. Table 1 provides a summary of each rating category and breakdown among the dicots, monocots and pteridophytes. As expected, the bulk of the at risk taxa are members of the magnificent evolutionary radiations arising from about 10% of the successful colonists (Wagner, 1991). Most of these are dicots. The tragic losses and declines have not been uniform among these radiations. Some of the genera have more at risk taxa than would be expected for their size, including *Schiedea* (100% at risk), and *Cyanea* (84%), while others such as *Bidens* (48%), *Clermontia* (48%), *Myrsine* (32%), *Peperomia* (12%), and *Wikstroemia* (29%) have fewer at risk taxa than would be expected. The reasons for this and other patterns relative to rarity are currently being explored by A.K. Sakai & Wagner (unpublished). For further information on the ecological problems brought about by human influence in the Hawaiian Islands and related conservation issues we refer the reader to pertinent recent literature such as (Cuddihy & Stone, 1990; Culliney, 1988; Kirch & Hunt, 1997; Meilleur, 1996; Mueller-Dombois & Fosberg, 1998; Stein & Flack, 1996, 1997; Stein *et al.*, in press; Stone *et al.*, 1992; Vitousek *et al.*, 1995) and other references they cite.

The overall list includes 266 taxa for which the authors do not give a current at risk status, designated as Apparently Secure (AS). Of these, 222 are ranked G3 or higher by HINHP with 150 of these not ranked in the US or IUCN systems. This is not surprising or inconsistent with our rankings as many of the G3 taxa in the HINHP database are sin-

gle island endemics and thus relatively rare and potentially of concern because of their narrow geographical range. However, 111 of the AS taxa in our list are given an at risk status (>50% of them R) in the *1997 IUCN red list*. It seems that the IUCN criteria used were more liberal than ours. All but 23 of these 111 were considered by HINHP to be G3 or higher. None of these 111 have been federally listed or proposed for listing. There are 32 taxa not included in any other system for which we give an “at risk” status rank. These are, with three exceptions (*Fragaria chiloensis*, *Liparis hawaiiensis*, and *Vigna adenantha*), all newly described taxa or taxa recently resurrected from synonymy of other species. In fact, many of the HINHP G3 taxa have not been given rankings in the other systems. These are taxa of concern, and are usually single island endemic taxa that are not necessarily strongly threatened or declining. Many more Hawaiian taxa were given at risk conservation status rankings in the *1997 IUCN red list* than we believe appropriate. We have included all of these taxa from the HINHP and IUCN lists in the overall list under our category of Apparently Secure (AS).

Abbreviations used in distribution statements in list

elev	elevation
EM	East Maui
end	endemic
ex	extirpated (follows immediately after geographical area in which a taxon is no longer known to occur)
FF	French Frigate Shoals (incl. Tern and other islands)
GP	Gardner Pinnacles
H	Hawai‘i Island
Hwy	Highway
HI	The eight main Hawaiian Islands (Ni‘ihau, Kaua‘i, O‘ahu, Moloka‘i, Lāna‘i, Maui, Kaho‘olawe, and Hawai‘i)
ind	indigenous
K	Kaua‘i Island
Ka	Kaho‘olawe Island
Kl	Ka‘ula Island
Ko	Ko‘olau Mountains, O‘ahu
Ku	Kure Atoll (incl. Sand and Green Islands)
L	Lāna‘i Island
La	Laysan Island
Le	Lehua Island
Li	Lisianski Island
M	Maui Island
Mi	Midway Atoll (incl. Sand and Eastern Islands)
MI	Molokini Island
Mo	Moloka‘i Island
Mt	Mount
Mtn	Mountain
Mts	Mountains
N	Nihoa Island
NP	National Park

NWI	Northwestern Hawaiian Islands
nat	naturalized
Ne	Necker Island
Ni	Ni'ihau Island
O	O'ahu Island (incl. Mokoli'i Islet)
PH	Pearl and Hermes Atoll
pol	Polynesian introduction
Pt	Point
Rd	Road
rds	roads
Wa	Wai'ananae Mountains, O'ahu
WM	West Maui

Acknowledgments

We appreciate assistance in database handling by Mike Sisson and Robynn Shannon at the Smithsonian Institution, Christa Russell at the U.S. Fish and Wildlife Service, and Roy Kam at The Nature Conservancy of Hawaii. We appreciate the assistance of Lucy Julian to transcribe the HINHP data into the Smithsonian database. This work was in part supported by a grant from the Smithsonian Scholarly Studies program. We also acknowledge the tremendous contribution the field botanists working currently in Hawai'i have made to this assessment. Knowledge of both the naturalized and native species has increased significantly because of this intensive field work, particularly collection efforts by Randy Bartlett, Tim Flynn, Bob Hobdy, Guy Hughes, Clyde Imada, Joel Lau, Dave Lorence, Arthur Medeiros, J. Scott Meidell, Ken Nagata, Hank Oppenheimer, Steve Perlman, Robert Shaw (and associates), and Ken Wood. We appreciate comments on a draft of the introduction by Brien Meilleur, Vickie Caraway, Bruce Stein, and Mary Yurlina.
